1 Research question and project description

In our collaborative research project, we seeks to provide an answer to the following question: **How the rise in the rise in inequality and economic growth influences the purchase of luxury goods, particularly cars, and the usage of public transportation systems in Singapore, from 1995 to 2015**. Therefore, we collected data on economic growth, income inequality, usage of public transports and purchase of cars covering the time span of 20 years, from 1995 until 2015. As suggested by our research question, economic growth, income inequality and usage of public transports are the explanatory variables, while purchase of cars is the dependent variable. The reason why we chose cars as example of luxury goods showing social status, is that in Singapore purchasing of cars is particularly expensive, due to high taxation and a certificate of car entitlement, whose cost can be higher than 70.000 dollars. For more details about the research proposal and case justification see ResearchProposal.

2 Processing data

2.1 Data sources and data gathering

The data that we need for our empirical analysis are to be retrieved from different sources:

- IMF Cross Country Macroeconomic Statistics open data, containing cross-country marcoeconomic data.From this source we downloaded the dataset on Singapore GDP per Capita at Current Prices measured in national currency from 1980 until 2020 (forecasts). Data were downloaded in csv format (selecting only the time span of interest) from Quandl, a website providing high-quality financial and economic data in different formats to facilitate data analysis.

- Knoema, a knowledge platform connecting data with analytical and presentation tools, in order to allow users to access, present and share data-driven content. From The World Top Incomes Database - providing access to data on the distribution of top incomes in more than twenty five countries across the globe - we downloaded data about the top 10% average income (https://knoema.com/mzqtlyd/the-worlds-top-incomes-database?tsId=1010250& action=download&action=download&action=download) and bottom 90% average income (https://knoema.com/mzqtlyd/the-worlds-top-incomes-database?tsId=1010250&action=download& action=download&action=download) in Singapore. However, since data were available only until 2009, the values of bottom 90% and top 10% average income for the years 2010 - 2015 were forecasted with a regression and included in the original dataframe. These data were then compared in order to understand how many times the top 10% average income is higher than the 90% average income. The reason why we did not gather data from the database ClioInfra available on Quandl as we had defined in our ResearchProposal, is that it did not provide sufficient data for the time span we are considering.

- PUBLIC TRANSPORTS

- PURCHASE OF CARS

2.2 Cleaning and merging of datasets

After importing data on R and cleaning them, we merged the datasets. The final dataset has TOT observations. . . .

3 Descriptive and inferential statistics
